Prescriptive

Explaining and predicting behaviours

Basic principle

Discussion:

What would be potential variables to predict the following behaviours / the probability that a certain person behaves in that way (choose one):

- Number of restaurant guests to expect on a certain day
- Churn by mobile telecommunications customers
- Purchasing a book of a certain author
- Purchasing the new iphone
- Own example

Explaining and predicting behaviours

Application

- Purchase decisions (or in general: customer behavior) as an object and how it is influenced.
- Example PetCareRx
 - Supplies pet owners for 15 years
 - Products that need to be re-ordered every 3 to 12 months
 - Previously one-size-fits-it-all marketing approach with a set of possible discounts that are valid for all customers
 - Customer Analytics: customers were ranked according to their purchase probability
 - Discounts were differentiated on this basis
 - Result:
 - Higher margin with customers who had already decided to buy
 - Higher sales to customers who had not yet decided
 - In figures: 38% more sales, 24% more profit, 14% higher retention

Overview

(1) **Foundations** of Customer Analytics

(2) Analysing and predicting **customer retention**

(3) Analysing and predicting **cross buying / selling**

(4) Predicting **customer value**

(5) Differentiating customer behaviours: **customer segmentation**

CROSS BUYING

Cross-selling / Recommender systems / next product to buy

- Developing existing customer relationships further
- Better knowledge of customers (compared to non-customers)

CUSTOMER RETENTION

Explaining and Forecasting Customer Retention

– Relevance –

- Customer retention cheaper than customer acquisition
- „Socialising cost“
- „Pole position“
- Accessibility

Customer churn rate in the United States in 2020, by industry

Typical determinants of customer retention

- Customer perceptions:
 - Customer satisfaction
 - others
- Relationship characteristics:
 - Length of relationship
 - Breadth of relationship (e.g. number of different product categories)
- Demographics (?)
- ...

Churn prediction – Basic approach

$$\ln \left(\frac{P(\text{Churn} = 1)}{1 - P(\text{Churn} = 1)} \right) = \beta_0 + \beta_1 \cdot \text{Tenure} + \beta_2 \cdot \text{Contract}_{\text{Monthly}} + \beta_3 \cdot \text{MonthlyCharges} + \beta_4 \cdot \text{ServiceCalls}$$

Variable	Coefficient (β)	Odds Ratio
Intercept	-2.10	-
Tenure (years as customer)	+0.25	1.28
Contract_Monthly (1 = month-to-month, 0 = annual)	+0.30	1.35
Monthly charges (in 10 CHF increments)	+0.55	1.73
ServiceCalls (Number of customer service contacts, last 3 months)	-0.60	0.55

Churn prediction – Basic approach

Attribute	Value
Tenure	1 year
Contract type	Month-to-month (=1)
Monthly charges	€70 (→ value 7 in €10 increments)
Service calls (3 months)	2

Step 1 — Compute the log-odds:

$$z = -1.20 + (-0.35 \times 1) + (1.10 \times 1) + (0.15 \times 7) + (0.45 \times 2)$$
$$z = -1.20 - 0.35 + 1.10 + 1.05 + 0.90 = 1.50$$

Step 2 — Convert the log-odds to a probability (sigmoid function):

$$P(\text{Churn}=1) = 1/(1+e^{-z}) = 1/(1+e^{-1.50}) \approx 0.82$$

→ **Customer A has an estimated churn probability of approximately 82% —**
a clear candidate for a retention offer.

Irit Nitzan & Barak Libai

Social Effects on Customer Retention

Journal of Marketing
Vol. 75 (November 2011), 24–38

Forecasting customer retention

Case: Social influence on customer churn

Variables:

- Exposure: Presence of previous defectors in the social system of a defector
- Tie strength:
 - Volume of communication between each pair of customers as an indicator of the strength of the tie between those customers
 - Sum of minutes these customers spent talking (conversations initiated by either of them) and the number of text messages they exchanged
- Homophily: Percentage of similar characteristics a pair of connected customers share
- Degree: Number of unique persons with whom this customer communicated during the first three months of data
- Satisfaction indicators:
 - Number service records
 - Level of usage: $\text{Usage current month} / \text{Usage 3 previous months}$

Forecasting customer retention

Case: Social influence on customer churn

Variable	Unit of Analysis	Model 1 Traditional Model		Model 2 Social Model	
		Parameter Estimate	Hazard Ratio	Parameter Estimate	Hazard Ratio

Overview

- (1) **Foundations** of Customer Analytics
- (2) Analysing and predicting **customer retention**
- (3) Analysing and predicting **cross buying / selling**
- (4) Predicting **customer value**
- (5) Differentiating customer behaviours: **customer segmentation**

CROSS BUYING

Cross-selling / Recommender systems / next product to buy

- Developing existing customer relationships further
- Better knowledge of customers (compared to non-customers)

CROSS BUYING

Cross-selling / Recommender systems / next product to buy

TESCO
Every little helps

Cross buying

- Cross-selling in the customer relationship life cycle
- "Recommender systems", Amazon as a role model
- Example:
 - US cosmetics supplier with numerous stores
 - Goal: Personalization of communication with several 100'000 customers
 - Analysis: Cluster-based targeting and personalized recommendations
 - Predictive analytics for the formation of product-based clusters (e.g. "bath and beauty", "face cream")
 - Segment specific email campaign
 - Increase in sales per email by 600%

Cross buying

Definition

Cross-buying refers to a customer's tendency to purchase additional products or services from the same company, beyond their initial purchase, expanding the breadth of the customer-firm relationship.

Why it matters

- Cross-buying customers are typically **more profitable** and **more loyal**. A broader product portfolio increases switching costs and relationship depth
- Acquiring an *additional* product from an existing customer is generally cheaper than acquiring a new customer
- Cross-buying is often used as a leading indicator of relationship strength, alongside retention and share-of-wallet

Key distinction

- *Cross-buying* = will the customer purchase an additional **category**? (binary outcome)
- *Next-Product-to-Buy (NPTB)* = **which specific product**, among several, will they buy next? (multi-category outcome)

Cross buying

Fictive example: Model

$$\ln \left(\frac{P(\text{CrossBuy} = 1)}{1 - P(\text{CrossBuy} = 1)} \right) = \beta_0 + \beta_1 \cdot \text{Tenure} + \beta_2 \cdot \text{Satisfaction} + \beta_3 \cdot \text{ProductsOwned} + \beta_4 \cdot \text{Complaints}$$

Cross buying

Fictive example: Application to individual customer

Scenario: An insurance company wants to estimate the probability that an existing car-insurance customer will also purchase home contents insurance.

Model (fictive coefficients, binary logistic regression):

Variable	Coefficient (β)	Odds Ratio
Intercept	-2.10	-
Tenure (years as customer)	+0.25	1.28
Satisfaction (Scale 1-10)	+0.30	1.35
Products already owned	+0.55	1.73
Complaints (last 12 months)	-0.60	0.55

Customer "Ms. K.": 5 years as customer, satisfaction 8/10, already owns 2 products (car + liability insurance), no complaints.

Step 1 — Compute the linear predictor (log-odds):

$$z = -2.10 + (0.25 \times 5) + (0.30 \times 8) + (0.55 \times 2) + (-0.60 \times 0)$$

$$z = -2.10 + 1.25 + 2.40 + 1.10 = 2.65$$

Step 2 — Convert to a probability:

$$P(\text{CrossBuy} = 1) = \frac{1}{1 + e^{-2.65}} \approx 0.93$$

→ **Ms. K. has an estimated cross-buying probability of 93%** — an excellent candidate for a targeted home-contents insurance offer.

Case ING Diba

Rationale for Scoring Models

- ▶ Bank wants to push sales of a certain product knowing that demand for the specific product is varying among customers
- ▶ Bank knows **today's** customer data (collected over time)
- ▶ Based on existing customer data, bank wants to predict the customers most likely to buy the specific product within the **next X weeks** to include them into the sales campaign

Case ING Diba

Approach of scoring models

- (1) The bank knows all the customer data from a **certain point of time in the past**. Additionally, the bank knows who acquired a specified product **afterwards**
- (2) A **score model** can be calculated based on the **past data**, resulting in a **score value** (similar to a probability of purchase) for a specified product
- (3) The Score model can be applied to the bank's **current customer base** at any point in time, enabling the bank to sort customers by their score value and therefore by their probability of purchase

Case ING Diba

Case ING Diba

- Question: Which customer characteristics can explain high or low response rates in different subgroups?
- The principle task of a statistical analysis is to identify specific characteristics and to weight and combine them. A mathematical relation between response probability and customer characteristics can be established thereby.
- This relationship can be used for the prediction of future behavior.

The diagram illustrates a mathematical model for predicting response rates. It consists of five gray rectangular boxes arranged horizontally, each containing a customer characteristic and its weight. These boxes are connected by plus signs. The characteristics and weights are: 'Age x (0.7)', 'Gender x (1.5)', 'Income x (0.3)', 'Volume', and 'Purchasing power x (2)'. The final box is followed by an equals sign and the result '8,7%'. A small gray box with the word 'exemplary' is tilted and placed above the 'Purchasing power x (2)' box.

$$\text{Age x (0.7)} + \text{Gender x (1.5)} + \text{Income x (0.3)} + \text{Volume} + \text{Purchasing power x (2)} = 8,7\%$$

Case ING Diba

- The contacted customers are classified according to their expected response and divided into 10 groups:
 - Group 1 contains those 10% of customers with the highest expected response
 - Group 10 contains the customers with the lowest expected response
- The blue line shows the predicted numbers of response, the grey line shows the actually realized response rate during the campaign
- The prediction displays the actual response very well. The prediction is apparently able to select the „right“ response-affine customer. Trough the selection of „ideal“ clients the response is usually increased by about 50 percent.

Case ING Diba

Cross-selling potentials

-Procedure for mailings: Customers with the highest response probability for a certain product are contacted

-Cross-selling probability

	Product 1	Product 2	Product 3
→ Client 1	1.6%	0.3%	1.1%
→ Client 2	2.9%	0.9%	0%
→ Client 3	0%	1.2%	2.0%
→ Client 4	2.0%	0.4%	1.3%
→ Client 5	1.5%	0.3%	1.1%
→ Client 6	2.9%	0.9%	0%
→ Client 7	0%	1.2%	2.0%
→ Client 8	2.0%	0.4%	1.3%

-Procedure for "next best offers" for inbound contacts :

- ➔ Response probability for each customers and each products is calculated
- ➔ The product with the highest response probability is recommended

-Cross-selling probability

	Product 1	Product 2	Product 3	
➔ Client 1	1.6%	0.3%	1.1%	
➔ Client 2	2.9%	0.9%	0%	Recommendation for client 2: product 1
➔ Client 3	0%	1.2%	2.0%	
➔ Client 4	2.0%	0.4%	1.3%	
➔ Client 5	1.5%	0.3%	1.1%	
➔ Client 6	2.9%	0.9%	0%	
➔ Client 7	0%	1.2%	2.0%	
➔ Client 8	2.0%	0.4%	1.3%

RFM Analysis

RFM analysis is one of the oldest and most widely used methods in database marketing. Key references include **Hughes (1994)**, "Strategic Database Marketing", and **Bult & Wansbeek (1995)**, "Optimal Selection for Direct Mail", *Marketing Science*. The latter showed that RFM variables are strong predictors of response probability and customer value, and integrate well into response and profitability models.

Core idea: Three simple but highly informative behavioral variables are often sufficient to segment customers:

Dimension	Meaning	Interpretation
R ecency	How long ago was the last purchase?	Recently active customers are more likely to buy again
F requency	How often has the customer purchased?	Frequent buyers are more loyal
M onetary	How much has the customer spent in total?	Higher spend = higher customer value

RFM Analysis: Scoring approach

The classic approach divides the customer base into **quintiles** (5 equally sized groups) for each dimension, typically scored from 1 (worst) to 5 (best):

Recency: Customer with the most recent purchase → score 5; longest time since last purchase → score 1

Frequency: Customer with the most purchases → score 5; fewest purchases → score 1

Monetary: Customer with the highest spend → score 5; lowest spend → score 1

The three scores are combined into an **RFM code** (e.g., "5-4-5"), which serves as the basis for segmentation and target group selection.

RFM Analysis - Example

Customer	Days Since Last Purchase	Number of Purchases (12 mo.)	Total Spend (€)
A	5	18	2,400
B	90	3	350
C	12	12	1,800
D	200	1	120
E	30	8	950

Customer	R-Score	F-Score	M-Score	RFM Code
A	5	5	5	555
B	2	2	2	222
C	5	4	4	544
D	1	1	1	111
E	4	3	3	433

- (1) Foundations** of Customer Analytics
- (2) Analysing and predicting **customer retention**
- (3) Analysing and predicting **cross buying / selling**
- (4) Predicting **customer value**
- (5) Differentiating customer behaviours: **customer segmentation**

Customer segmentation / Personas

Effectiveness

Efficiency

Behavioural customer segmentation

Using product-based customer segments

Sports article retailer:

- Original assumption: Soccer mums = Yoga mums
- Cluster analysis result:
 - Segment 1: Soccer and baseball mums
 - Segment 2: Yoga mums

Case vitamine / wellness brand:

- Assumption that a certain product was bought by elderly customers
- Data analysis shows that the body builder segment were main users of the product

Customer segmentation criteria

Requirements for segmentation criteria

- Relevance for purchasing behaviour
- Relevance for defining marketing measures
- Accessibility
- Measurability
- Stability
- Efficiency

Behavioural customer segmentation

- Segmentation based on customer behaviours
- Examples:
 - Channel usage
 - Response to discounts
 - Recency, frequency, monetary (RFM)
- Objective: e.g. 6-8 clusters
- Each cluster with its own „cluster DNA“ which makes it different from other clusters
- Typically start with numerous variables which are reduced to e.g. 10 variables which determine the clusters

- k-means clustering
- Hierarchical clustering
- Density-based clustering (DBSCAN / HDBSCAN)
- Latent Class Analysis (model-based clustering)
- Autoencoder-based clustering (Deep Embedded Clustering)
- Self-Organizing Maps (Kohonen networks)
